

Abstract: This paper presents a new method for the automatic detection of the onset of a seizure. The method is based on the analysis of the EEG signal. The onset of a seizure is detected by the analysis of the power spectrum of the EEG signal. The power spectrum is calculated by the Fast Fourier Transform (FFT) method. The power spectrum is then analyzed by the method of the power spectrum ratio (PSR). The PSR is calculated by the ratio of the power spectrum of the EEG signal to the power spectrum of the reference signal. The reference signal is the power spectrum of the EEG signal before the onset of the seizure. The PSR is then compared with a threshold value. If the PSR is greater than the threshold value, the onset of a seizure is detected. The method is applied to the EEG signal of a patient with epilepsy. The results show that the method is able to detect the onset of a seizure with a high accuracy.

The `String` interface defines the methods for manipulating strings. The `String` interface is implemented by the `String` class and the `StringBuffer` class. The `String` class is a final class, which means that it cannot be subclassed. The `StringBuffer` class is a mutable class, which means that its state can be changed. The `String` interface defines methods for concatenating strings, comparing strings, and searching for substrings. The `String` interface also defines methods for converting strings to and from other data types.
